## Objectives

- Review the body of literature about the gut microbiome in health & IBD over the last decade
- Understand if diet and enteral nutrition determine the gut microbiome and to critically review if microbiome influences the diagnosis and treatment in IBD
- Speculate how the emerging discoveries of gut microbiome can help clinicians manage IBD in day-to-day practice

## The Gut Microbiota in Health and Disease

◆ Food, antibiotics, xenobiotics and host genetics shape the composition of the gut microbiota

◆ Diet, and the derivatives serve as substrates for the gut microbiota to produce metabolites

\*Children's Healthcare of Atlanta | Emory University

## The Gut Microbiota

- There are **100 trillion** bacteria that live in our GI tract
- **10x** the number of "human" cells in our body
- **100x** as many genes as there are in the human genome

*We are more bacteria than we are human*

## The Gut Microbiota or The Microbiome

- There are **100 trillion** bacteria that live in our GI tract
- **10x** the number of "human" cells in our body
- **100x** as many genes as there are in the human genome

- Microbial colonization starts at birth
- This partnership has evolved over thousands of years

## First 3 years of life – Microbiota is highly variable “The sensitive period”

Phylogenetic composition of bacterial communities evolves toward adult composition over the first **three years of life** in all populations

Nature 486: 222, 2012

Science 331: 337, 2011

## Microbiota diversity increase with age

Least diverse in > 50 yr old men

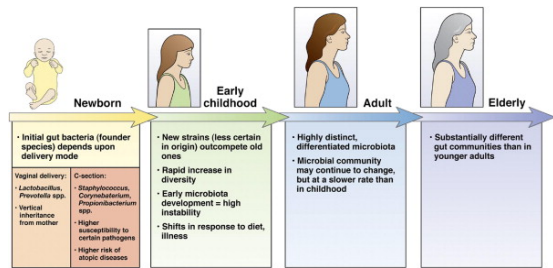

Bacterial diversity increases with age in all populations. Fecal microbiota of US adults is the least diverse.

## 16sRNA: Culture-Independent Sequence Analysis of the Microbiome

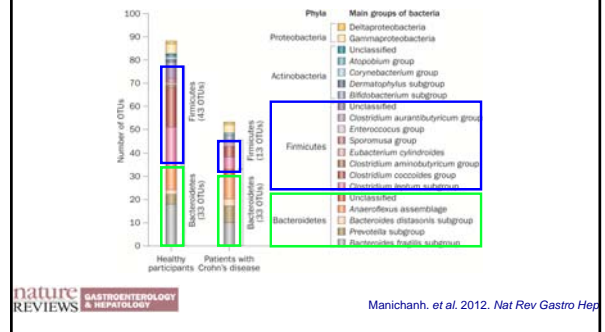

- Found in all bacteria
- Highly conserved
- Hypervariable regions provide species-specific signature sequences
- Useful for bacterial identification
  - qPCR
  - 16s gene sequencing
  - High throughput

## GUT MICROBIOME - Terminology

- **Dysbiosis:** Altered microbiota composition either quantitatively, qualitatively or both
- **Alpha diversity:** Alpha diversity (intrinsic measure): a measure of species richness or diversity within an individual sample (how many types of microbial sequences in a sample)
- **Beta diversity:** Beta diversity (comparative measure): is a term for the comparison of samples to each other (how many different types are distributed between samples)
- **Enterotypes of gut microbiome:** abundance of bacteria; usually one of the 3 genres - bacteroids, prevotella or ruminococcus
- **OTUs: Operational taxonomic units:**

## Dietary components regulate bacterial gene transcription

- Important function of the intestinal microbiome is metabolism of glycans (complex carbohydrates and polysaccharides)
- Bacteroides thetaiotaomicron*
  - Highly abundant obligate anaerobe in the microbiota of most adults
  - Known for its ability to metabolize polysaccharides

Polysaccharide-rich diet

# Diet, the Gut Microbiome, Metabolome, and Disease

•Diet serves as a substrate for the microbiota to produce certain metabolites

**A** Lumen (Microbiota-Rather interactions) Intestinal Wall (Microbiota most direct interactions) Host metabolites of microbial-derived metabolites

The diagram illustrates the pathway from diet to host health through the gut microbiome and metabolome. It is divided into three main sections: Lumen (Microbiota-Rather interactions), Intestinal Wall (Microbiota most direct interactions), and Host metabolites of microbial-derived metabolites.

**Lumen (Microbiota-Rather interactions):** This section shows the breakdown of dietary components by various enzymes and microbes. Dietary Choline Metabolites are broken down by Bifidobacterium, Clostridia, and Lactobacillus. Other dietary components like Phospholipids, Starch, and Protein are broken down by Amylase, Lipase, and Protease, respectively. Microbial Acid Metabolites are produced by Clostridia, Bifidobacterium, and Lactobacillus.

**Intestinal Wall (Microbiota most direct interactions):** This section shows the interaction of these metabolites with the intestinal wall. Dietary Choline Metabolites are converted to Trimethylamine (TMA) and then to TMAO. Microbial Acid Metabolites are converted to Short Chain Fatty Acids (SCFAs). Other metabolites like Phenylglyoxal, Oxidized LDL, and Oxidized Phospholipids are also shown.

**Host metabolites of microbial-derived metabolites:** This section shows the final products of these interactions, which are then used by the host. These include Neurotransmitters, Short Chain Fatty Acids, Phenylglyoxal, Oxidized LDL, Oxidized Phospholipids, and Microbiota produced vitamins (Vitamin K, B12, and others). These metabolites are then used by the host to produce various health outcomes, including Lymphatic Vessels, Liver, Heart, and Kidney.

**Host Health Outcomes:** The final outcomes of these interactions are Lymphatic Vessels, Liver, Heart, and Kidney. The diagram shows that these outcomes are influenced by the metabolites produced by the microbiome and the host's metabolism.

- Involves 28 pediatric IBD centers in USA/CAN
- Inception cohort (diagnostic sample)
- Sampled before treatment initiation
- Total of 1,100 children with CD (1,700 participants)
- Samples: blood, ileal & rectal biopsies, stool
- Host genetics, mucosal gene expression, serology, & microbiome

## The Microbiome shifts in pediatric Crohn's disease

## The dysbiosis presents itself as a gradient across the patient population

## Antibiotic exposure amplifies the microbial dysbiosis

## Determining the key players of microbial dysbiosis in new-onset pediatric CD – RISK study

- We identified microbial organisms associated with subject's disease phenotype (controlled for confounding variables, such as past antibiotic use, age, gender, and race)
- Several taxa were reported before, including Enterobacteriaceae, Bacteroidales, and Clostridiales.
- We identified additional taxa as significant biomarkers for disease, including members of the Pasteurellaceae, Veillonellaceae, Neisseriaceae, and Fusobacteriaceae.
- Antibiotic exposure amplifies the microbial dysbiosis, by further loss of *Bacteroides*, *Clostridiales*, and *Erysipelotrichaceae*, and increase in *Fusobacteriaceae* and *Enterobacteriaceae*

## Subjects-Methods

- 19 active CD and 21 healthy controls
  - four were excluded (antibiotics)
- 8 weeks on EEN (Modulen®, Nestle)
  - 4 samples during EEN (0, 15, 30, 60 d) and one when back on free diet (2-4 months post EEN)<sup>1,2</sup>
- 12/15 clinically improved & faecal calprotectin decreased<sup>1,2</sup>
- Next generation sequencing (Illumina, MiSeq & HiSeq)
  - 16S rRNA (n=127) for taxa assignments (Genera, OTU, Oligotypes<sup>3,4</sup>)
  - Whole genome sequencing (n=96) (metabolic pathways-KEGG modules)

## Crohn's Disease VS Controls

## Impact of EEN on microbial diversity

## EEN clearly differentiated before and after treatment

## Genetic Metabolic Capacity (WGS)

- Higher level of metabolic capacity in CD
- Tendency to decrease during EEN

•Children's Healthcare of Atlanta | Emory University

## Conclusion: EN and Microbiota

- CD microbiota less diverse but with a wider functional capacity
- Several genera/OTU and metabolic pathways changed during EEN
  - Some correlated with calprotectin (*Atopobium*) and other not (*F. Prausnitzii*)
- EEN may work by suppressing
  - a) The entire microbiota in CD, thus inducing a lower antigenic effect to the gut
  - b) Bacteria associated with CD but also other sensitive to EEN composition
- Causative association or collateral effect?
  - Maintenance of these changes may prolong disease remission?
