Conflict of Interest: Dr. Sherman has received honoraria for CME presentations from Nestle Nutrition, Abbott Nutrition, and Mead Johnson Nutrition, and collaborates on research grants related to probiotics awarded from the Canadian Institutes of Health Research, Lallemand Human Nutrition, and BioKPlus. The other authors have indicated they have no potential conflicts of interest to disclose.

Contributors' Statement page

All authors meet the full criteria of authorship.

Prof Guarino and Dr Lo Vecchio conceptualized and designed the study, drafted the initial manuscript, and reviewed and revised the manuscript.

Dr Lo Vecchio and Dr Liguoro reviewed relevant guidelines and consensus statements on the management of acute diarrhea in infants and children between 1 month and 18 years of age published in one of the three most spoken languages (English, Chinese and Spanish) in the last 10 years.
Dr Dias, Dr Berkley, Dr Boey, Dr Cohen, Dr Cruchet, Dr Salazar-Lindo, Prof Sandhu, Dr Sherman, Dr Shimizu revised the article critically for important intellectual content.

Dario Bruzzese is the statistician who analyzed the data.

All authors approved the final manuscript as submitted and agree to be accountable for all aspects of the work.
ABSTRACT

Objectives. Despite a substantial consistency in recommendations for the management of children with acute gastroenteritis (AGE), a high variability in clinical practice and a high rate of inappropriate medical interventions persist in both developing and developed countries.

Aim of this study was to develop a set of clinical recommendations for the management of non-severely malnourished children with AGE to be applied worldwide.

Methods. The Federation of International Societies of Pediatric Gastroenterology, Hepatology, and Nutrition (FISPGHAN) Working Group (WG) selected care protocols on the management of acute diarrhea in infants and children aged between 1 month and 18 years. The WG used a 3-step approach consisting of: 1) systematic review and comparison of published guidelines, 2) agreement on draft recommendations using Delphi methodology and 3) external peer-review and validation of recommendations.

Results. A core of recommendations including definition, diagnosis, nutritional management and active treatment of AGE were developed with an overall agreement of 91% (range 80 to 96%). Twenty-eight world experts in pediatric gastroenterology and emergency medicine successively validated the set of 23 recommendations with an agreement of 87% (range 83 to 95%). Recommendations on the use of anti-diarrheal drugs and antiemetics received the lowest level of agreement and need to be tailored at local level. Oral rehydration and probiotics were the only treatments recommended.

Conclusions. Universal recommendations to assist health-care practitioners in managing children with AGE may improve practitioners’ compliance with guidelines, reduce inappropriate interventions and significantly impact clinical outcome and health-care associated costs.
Key words: Gastroenteritis, diarrhea, guidelines, recommendation, children

Abbreviations: Federation of International Societies of Pediatric Gastroenterology, Hepatology, and Nutrition (FISPGHAN); Working Group (WG); Acute Gastroenteritis (AGE); Oral Rehydration Solution (ORS); ReSoMal (Rehydration Solution for Malnutrition).

What is known:

- Comparing documents published in different countries, there is substantial consistency in guideline recommendations for children with acute gastroenteritis
- High variability exists in clinical practice
- Inappropriate medical interventions and a sub-optimal adherence to recommendations persist both in developing and more developed areas.

What is new:

- The development of universal recommendations, supported by evidence, public health authorities and pediatric societies (general pediatrics, pediatric gastroenterology, emergency care and infectious diseases), would be of value to health-care providers
- These guidelines would fill an unmet need in improving the outcomes of children with acute diarrhea, increasing the likelihood of meeting global targets.
INTRODUCTION

Under-5-year children’s mortality declined by more than half from 1990 to 2015. However, the Millennium Development Goal 4 target of a two thirds reduction was not met and the majority of deaths in children worldwide still derive from preventable infectious diseases (1). Among those, acute gastroenteritis (AGE) is the second leading cause of child mortality and morbidity, particularly in low-income countries. Although 30% reduction in mortality for diarrhea has been achieved in the last years, AGE still accounts for 550,000 deaths per year in infants and children under 5 years of age (2).

In high-income areas, mortality is a rare outcome, but AGE is a major cause of medical consultation and hospitalization resulting in a high health-care and economic burden (3, 4).

Although there is substantial consistency in guideline recommendations for children with AGE, a high variability in clinical practice, a substantial number of inappropriate medical interventions and a sub-optimal adherence to recommendations persist worldwide (5-10). There is evidence in different settings that providing a limited number of consistent recommendations may increase physicians’ compliance with standard of practice (11, 12).

In this scenario, the Federation of International Societies of Pediatric Gastroenterology, Hepatology, and Nutrition (FISPGHAN) Working Group (WG) for AGE identified the reduction of inappropriate medical interventions and the large-scale implementation of effective recommendations as two of the three highest priorities in order to reduce the burden of AGE in children worldwide, the third intervention was the use of e-learning as a tool to increase dissemination (13).
The WG considered that developing universal recommendations, supported by evidence, public health authorities and pediatric societies (general pediatrics, pediatric gastroenterology, emergency care and infectious diseases), would fill an unmet need in improving the outcomes of children with AGE, increasing the likelihood of meeting global targets. The aim of this work was to develop a core of consensus clinical recommendations for the management of non-malnourished children affected by AGE worldwide.

METHODS

In order to identify common definitions and recommendations for the management of acute diarrhea in children worldwide, FISPGHAN WG used a 3-step approach: 1) systematic comparative review of published guidelines, 2) agreement on draft recommendations and 3) external validation of universal recommendations (Figure 1A).

Phase 1

Included a review of guidelines and consensus statements on AGE management in subjects between 1 month and 18 years of age published in one of the three most spoken languages (English, Chinese and Spanish) in the last 10 years, using previously described methodology (5). According to results of phase 1, there is consensus on the main pillars for the management of AGE: definition of diarrhea, assessment of dehydration, oral rehydration, age-appropriate diet, and possible use of selected products that could reduce the severity and duration of diarrhea (5).
Phase 2

The steering committee proposed definitions and recommendations aimed at managing children with AGE worldwide. This list was circulated to members of FISPGHAN WG to obtain their comments and corrections. Not essential recommendations were eventually removed. The Delphi method was used to reach an agreement (Figure IA) (14).

Subsequently, all members expressed their agreement by a 5-point Likert Scale (Round 1), a valuable tool used to compare and rank ordinal data (15). A specific target category of the scale was identified as referral category ("strongly agree" category) and the target consensus measure was calculated and expressed as a value between “0” and “1”.

The overall agreement and the agreement for each recommendation were finally expressed as percentage. Those recommendations that did not reach at least 80% agreement in the first round, were re-discussed and tailored, and the entire list of recommendations was again scored with the same methodology (Round 2). Once all recommendations reached ≥80% agreement, a new list of recommendations was developed (Figure IA).

Since malnutrition may significantly change the approach to children with AGE, the list of recommendations developed by the WG applies to well-nourished to non-severely malnourished children. This point was specifically highlighted in the final list of recommendations.

Phase 3

In Phase 3, an electronic questionnaire reporting definition and recommendations was circulated among 50 experts around the world (including at least 5 from each continent). We invited clinicians and/or researchers, members of the World Societies for Pediatric Gastroenterology,
Hepatology and Nutrition, of WHO and of European Society of Pediatric Infectious Diseases and Societies of Pediatric Emergency Medicine to participate.

Each participant was asked to express his/her agreement on each recommendation; the calculation of overall agreement was performed by the methodology previously reported.

A recommendation was finally accepted only if at least 75% external experts provided their agreement. The recommendations not reaching this threshold were discussed in the text but not included in the final set of recommendations.

RESULTS

Figure 1 B shows the results obtained in each phase. The results of Phase 1 were reported in detail in a previous publication (5). However, starting from the evidence obtained in Phase 1, the steering committee developed a list of 28 definitions/recommendations. After circulation of this list among the WG members, one recommendation was removed, two recommendations on the use of anti-emetics were combined together and a new recommendation on treatment was added, resulting in a final list of 27 recommendations.

In Round 1, the raters expressed an overall agreement of 86% (range 70 to 98%) with 6 recommendations rating < 80%. In Round 2, the overall agreement increased to 91% (range 81 to 98%), with two recommendations on the pharmacological treatment with Smectite and Racecadotril showing a grade of agreement below 80% (76 and 78%, respectively) (Figure 1B).

Twenty-eight out of 50 experts took part in the third phase of the project (Response rate 56%). After Round 3, four recommendations focusing on the dehydration scores (1 recommendation),
the use of antiemetics (1 recommendation) and specific antidiarrheal drugs (2 recommendations) did not reach the threshold of 75% agreement and were excluded from the final set of recommendations. The overall agreement expressed by the external experts was 87%. The agreement received by single recommendations in each Phase of the study is reported in Table 1.

Below are the definitions and recommendations developed by the FISPGHAN WG and, subsequently, validated by external revision and voting:

**Definitions**

Several definitions have been used by researchers, scientific societies and health-care authorities to describe acute infectious diarrhea in childhood. Johnston et al. analyzing the clinical trials published in pediatric age, found 64 unique definitions of diarrhea and 69 definitions of diarrhea resolution (16). Starting from the definitions used by other guidelines collected in the Phase 1, the WG agreed upon the following definition.

**Recommendation 1 (Agreement 85%)**

Acute gastroenteritis (AGE) is characterized by the presence of diarrhea defined as a decrease in the consistency of stool leading to loose or liquid stools and/or an increase in the frequency of evacuations to three or more in 24 hours, with or without fever or vomiting.

- Acute diarrhea lasting 7 days or less.
- Prolonged diarrhea lasting 8 to 13 days
- Chronic or persistent diarrhea lasting 14 days or more
Assessment of dehydration

Dehydration is the consequence of diarrhea, vomiting and fever. It is a major risk for child health and the main reason for medical visit, hospitalization and cause of death. Assessing dehydration in a reliable and rapid way is essential to prevent severe dehydration and its consequences and promptly start treatment.

Recommendation 2 (Agreement 86%)

The percentage of body weight lost is the best measure of dehydration. However, in most circumstances, pre-illness weight is frequently not available to estimate weight lost during an episode of diarrhea.

Recommendation 3 (Agreement 84%)

Dehydration reflects disease severity particularly in the community setting. In hospitalized children, although dehydration may also be considered, other parameters (such as respiratory distress, deep breathing, signs of shock, inability to drink, neurological signs, electrolyte abnormalities or body weight loss) may also be used as markers of severity.

Recommendation 4 (Agreement 85%)

The best parameters to estimate the degree of dehydration are: skin turgor, sunken eyes, general appearance, capillary refill time and mucous membranes. These parameters are frequently included in clinical scores that may be used to estimate the degree of dehydration in individual children. Reliability of those signs may be reduced in malnourished children.

Although none of the available scoring systems for dehydration reached the threshold of 75% agreement, the Clinical Dehydration Scale (17) is commonly considered a reliable tool to estimate the degree of dehydration in non-malnourished children with AGE (agreement 74%).
This 4-item score system, based on the evaluation of general appearance, mucous membranes, eyes and presence of tears, has been mainly applied in high-income countries and has been recently demonstrated to be helpful in ruling in moderate-to-severe dehydration (≥6%) in this setting (18). However, its reliability needs to be better established in resource-poor settings.

**Diagnostic work-up**

Children otherwise healthy with AGE do not require a specific diagnostic work-up, since the results of laboratory and microbiological investigations are not likely to change their management. Diagnostic work-up may be required in selected cases.

*Recommendation 5 (Agreement 89%)*

In most cases, children with AGE do not require any diagnostic workup. In severe conditions and/or in the hospital setting, investigations may be appropriate in individual cases.

*Recommendation 6 (Agreement 91%)*

Children presenting with uncomplicated AGE do not require routine of microbiological investigation.

*Recommendation 7 (Agreement 90%)*

Microbiological investigations should be considered in the following circumstances:

- Children with underlying chronic conditions (e.g. oncologic diseases, IBD, immunodeficiency)
- Extremely severe clinical conditions (e.g. sepsis)
- Prolonged symptoms (> 7 days)
- During outbreaks (childcare, school, hospital)
- Children with severe bloody diarrhea and high fever
- History of travel to at-risk areas

**Rehydration**

Replacing fluid losses and avoiding dehydration are the primary aims of AGE management.

The oral route is effective in preventing and treat mild-to-moderate dehydration and should be started as soon as possible with appropriate solutions.

Different oral rehydration solutions (ORS) are available worldwide, however, an overall trend in recommending reduced osmolarity solutions (60-75 mmol Na⁺) has been observed in the last 10 years based on evidence of efficacy and better palatability than the WHO/UNICEF 90 mmol Na⁺ ORS. Different ORS compositions may show some different efficacy according to spread of *Vibrio cholerae* and the prevalence of malnutrition. In any case, the use of ORS is the key intervention to reduce AGE-related mortality, and it should be explained to mothers at wellbeing visits particularly in low-income areas as early as possible.

In children who do not tolerate oral rehydration, enteral or intravenous rehydration may be needed, however, a rapid switch back to oral route significantly reduces side effects and improves recovery.

*Recommendation 8 (Agreement 94%)*

Oral Rehydration Solution (ORS) is the first-line treatment of AGE.

Knowledge, attitude and practice about oral rehydration by health service providers are essential and should be promoted.

*Recommendation 9 (Agreement 88%)*
Reduced osmolality ORS (60-75 mmol/L Na+) is recommended as first-line treatment of AGE.

In case of cholera 75 mmol/L Na+ is the standard rehydration regimen.

**Recommendation 10 (Agreement 76%)**

ReSoMal (Rehydration Solution for Malnutrition) containing 45 mmol/L Na+ and 40 mmol/L K+ may be indicated for malnourished children although there are no conclusive data on its efficacy compared to standard reduced osmolality ORS.

**Recommendation 11 (Agreement 83%)**

In children who fail on oral rehydration, administration of rehydration fluids either by nasogastric tube (NGT) or intravenously (IV) is effective and should be recommended. IV rehydration should be avoided where possible in severely malnourished children.

Children with shock should be managed according to guidelines for hypovolemic shock. In non-shocked children with severe dehydration, moderate-quality of evidence supports the use of rapid IV rehydration with 20 mL/kg/hour of 0.9% saline solution for 2 to 4 hours. These rehydration regimens have been proposed in high-income settings and need to be tested in other settings before providing recommendations.

**Recommendation 12 (Agreement 89%)**

Enteral administration of ORS through a NGT is effective in rehydrating children with AGE and it is associated with fewer side effects than IV rehydration, especially in malnourished children.

Its knowledge, attitude and practice should be promoted amongst health workers as well as families and local workers.
Nutritional management

Several nutritional approaches are currently used worldwide according to local habits and beliefs to reduce severity and duration of diarrhea, but only few have been appropriately tested for efficacy. All international guidelines agree on continuation of breast-feeding throughout the episode, and an age-appropriate scheme should be started during or after initial rehydration (4–6 hours). Diet modification is usually unnecessary. However, several data support the addition of Zinc to malnourished children.

Recommendation 13 (Agreement 92%)

Infants < 6 months should not interrupt breastfeeding nor introduce diluted or modified formula. Where there is not the possibility to breastfeed, routine dilution of milk and routine use of lactose-free milk formula are not usually necessary.

Recommendation 14 (Agreement 91%)

Children should be re-fed early during the course of AGE. Regular oral feeding should be reintroduced no later than 4-6 hours after the onset of rehydration.

Recommendation 15 (Agreement 84%)

Lactose-free formula is generally not necessary in AGE episodes. However, lactose-restricted diets may be considered in hospitalized children and in children with prolonged diarrhea (> 7 days). Lactose-free formula should be recommended in children with chronic diarrhea (>14 days).

Recommendation 16 (Agreement 94%)

Elimination diet is usually not indicated for children with AGE and it may further impair the child’s nutritional status.
**Recommendation 17 (Agreement 85%)**

Zinc is recommended as an adjunct to oral rehydration therapy in children older than 6 months living in low-income countries or in settings with medium or high risk of zinc deficiency. Its efficacy is not supported by solid evidence in well-nourished children living in high-income countries. In infants below 6 months Zinc is not effective regardless of the nutritional status.

**Active treatment of diarrhea**

Many pharmacological interventions have been proposed in adjunct to ORS to reduce the severity and duration of symptoms. Only some have been specifically and accurately tested in clinical trials. Whereas, many products are currently available on the market with no proof of efficacy and safety. Children with diarrhea should receive only tested products. Physicians should discuss their use with families and caregivers explaining the modality of administration and expected effects, providing the important message that administration of any product should not replace oral rehydration therapy.

**Recommendation 18 (Agreement 84%)**

Active treatment of diarrhea with the administration of probiotics and/or drugs may be considered where there is solid proof of efficacy in reducing the intensity and duration of symptoms. To maximize efficacy, active treatment should be administered early in the course of the disease.

However, administration of any product should not replace oral rehydration therapy and should be always used as an adjunct to ORS treatment.
Because investigation of active therapies is rapidly evolving, the choice of best treatment should be always made along recommendations of evidence-based guidelines and in compliance with well-done RCTs.

Recommendation 19 (Agreement 79%)

Probiotics are effective in reducing the duration and intensity of symptoms of AGE. If available and in agreement with caregivers, selected probiotic strains (including *Lactobacillus rhamnosus* GG, *Saccharomyces boulardii* and also *L. reuteri* DSM 17938) can be considered in children with AGE, as an adjunct to ORS.

Antidiarrheal drugs recommended by several guidelines as adjunct to ORS treatment in children with AGE were considered for inclusion in the set of recommendations, but did not reach sufficient agreement among experts. Specifically, smectite (66.6%) and racecadotril (67.6%), that are recommended in guidelines produced in Europe, South America, Malaysia and China, were not endorsed based on our stringent criteria.

Recommendation 20 (Agreement 94%)

Loperamide and other antimotility drugs are not recommended in the treatment of AGE.

**Use of anti-emetics in children with AGE**

Vomiting is a major cause of dehydration (additional fluid losses and impaired oral rehydration). The use of antiemetics has been proposed with the primary aim of reducing vomiting in the first hours after disease onset, allowing effective oral rehydration and avoiding hospital admission. Routine use of antiemetics is still debated, mainly in the outpatients setting. However, if
prescribed, the potential side effects of antiemetics should be carefully taken into account by physicians.

*Recommendation 21 (Agreement 86%)*

A) Metoclopramide, although effective, has significant side effects and is therefore not recommended for children with vomiting due to AGE. The efficacy of domperidone is not supported by RCTs.

B) Ondansetron administered either orally or intravenously is effective in reducing vomiting and may avoid hospital admission. A single dose at the dosages used in the available studies may be considered in young children presenting to an emergency department with vomiting to ensure oral rehydration and reduce hospital admission. However, the use of ondansetron has been associated with QT prolongation and severe cardiac arrhythmias and the drug carries a warning label by both the FDA and the EMA that should be taken into account by health-care providers. Current cost of the product is also an issue that must be considered in many settings.

**Anti-infectious treatment**

AGE in otherwise healthy children is usually self-limited regardless of etiology. Even without specific antimicrobial therapy, clinical recovery generally occurs within a few days and the causative organism is cleared in a few days or weeks. Hence, an empiric anti-infectious treatment is not routinely indicated in children with AGE. An empiric antibiotic treatment may be considered in severe cases and in at-risk children with underlying chronic conditions or immunodeficiency. Overall, a pathogen-based approach within the local epidemiological pattern of antibiotic resistance should be considered only in particular circumstances.
Recommendation 22 (Agreement 95%)

Routine use of antibiotics is not recommended for the treatment of AGE.

Recommendation 23 (Agreement 84%)

The use of antibiotics should be started immediately and may be considered in specific situations, including:

- infants younger than 3 months
- children with underlying chronic conditions, including those with sickle cell anemia or immunodeficiency and those at risk of developing severe or extra-intestinal dissemination
- isolation of specific pathogens such as *Shigella*, Enterotoxigenic (but not Shiga-like toxin producing) *E.coli*, *V. cholerae*, *Yersinia enterocolitica*, and *Entamoeba histolytica*.
- *Campylobacter* colitis can be treated with antibiotics, but treatment is effective only if administered within the first two days from onset of symptoms.

DISCUSSION

Despite guidelines produced in different settings sharing similar recommendations for the management of children with AGE worldwide (5), a low adherence to standard indications and a significant variability in clinical practice have been widely reported (6-10).

The management of AGE is essentially based on 5 steps: 1) assessment of dehydration by simple, reproducible and validated parameters and/or clinical score, 2) prompt rehydration with reduced osmolality ORS, 3) avoidance of elimination diets and continuing of breastfeeding in infants and regular diet in children, 4) limiting laboratory investigations to selected
circumstances and increased risk of bacterial infection, 5) consider active treatment of diarrhea with products supported by compelling clinical evidence in children.

In 2012 the FISPGHAN WG identified the top priorities for the reduction of AGE burden worldwide (13) and now developed a set of clinical recommendations based on indications provided by guidelines produced in different countries and settings worldwide; the list has been validated by external experts in pediatric gastroenterology, emergency medicine and infectious diseases. The rate of agreement slightly decreased when the core of recommendations was circulated among external experts from different disciplines as expected. Nevertheless, an overall agreement higher than 85% was eventually achieved.

Some recommendations initially developed by the FISPGHAN WG were not validated by external experts and hence were not included in the final set of recommendations.

Overall, the FISPGHAN WG recommendations for the management of AGE in children closely match those of the World Health Organization (19), however relevant differences are present in treatment recommendations, including positive recommendation for selected anti-diarrheal products (i.e. selected probiotic strains) or antiemetics (in particular circumstances), indications to antibiotic treatment and negative recommendations for the use of zinc in not malnourished or zinc-deficient children.

The use of the Clinical Dehydration Score was proposed to assess dehydration in children with AGE. Although not included in final recommendations, the evidence reporting efficacy, reliability and ease use also by non-medical personnel, and an agreement of 74% suggest that Clinical Dehydration Scale could still be considered in clinical practice.
Routine use of antiemetics is mostly discussed in developed areas and emergency settings, where stopping vomiting to enhance oral rehydration can avoid hospital admission. Recent data supports a single oral dose of ondansetron in the emergency department (20, 21). However, the reports of potentially severe, but extremely rare, side effects hamper its use on a large-scale (22, 23); at least, until the warning will be cleaned by post-marketing analysis.

Recommendations for active treatment included effective probiotic strains but no drugs, including racecadotril and smectite.

This study has some limitations. First the WG set arbitrary thresholds to rule out or accept recommendations. A high threshold of 80% was set in the first two Rounds in order to exclude unnecessary and ambiguous recommendations and put the basis for a core set of recommendations. A slightly lower threshold (75%) was used in the third Round to include recommendations strongly agreed upon by experts from different pediatrics specialties.

Second, the paper did not discuss prevention of AGE in terms of public health and contacts measures or active immunization. The FISPGHAN WG identified rotavirus immunization as a public health priority and recently reported an unacceptably low vaccination rate in many countries also identifying costs and limited perception of rotavirus severity by public-health authorities, families and physicians as major barriers to local implementation (24).

Finally, the recommendations provided are not applicable to severely malnourished children. Although malnourished children are at higher risk of developing recurrent and complicated AGE episodes, only a few interventions have been tested in this population with variable results. For example, probiotics are considered a standard of practice in otherwise healthy children, but obtained inconsistent results in a malnourished population (25). We strongly believe that
malnutrition, and not geographical location, is the major determinant for considering changes in the management of AGE. Malnourished children need specific recommendations supported by evidence. However, irrespective of geographical setting, all other children may benefit from similar interventions and may be safely managed in the same way based on “universal” recommendations.

This paper is expected to increase adherence to effective management of AGE according to evidence-based indications.
